

Sir:

Transmitted herewith for filing is the Patent Application of:

Inventor: MOU-SHIUNG LIN

Title: HIGH PERFORMANCE SUB-SYSTEM DESIGN AND ASSEMBLY

Enclosed are:

- ☒ 9 sheets of drawing(s) - formal.
- ☐ An assignment of the invention to
- ☐ An associate power of attorney
- ☒ Statement Claiming Small Entity Status

The filing fee has been calculated as shown below:

	(Col. 1)	(Col. 2)		SMALL ENTITY
FOR:	NO. FILED	NO. EXTRA	RATE	FEE
BASIC FEE				\$380.
TOTAL CLAIMS	37 -20=	17	x 9.=	\$153.
INDEP CLAIMS	3 -3=	0	x 39.=	\$ .
MULTIPLE DEPENDENT CLAIM PRESENTED			+ 260 =	
			SUB TOTAL	\$533
			ASSIGNMENT	
			TOTAL	\$533

- ☒ Please charge my Deposit Account No. 19-0033 in the amount of \$533. A duplicate copy of this sheet is enclosed.
- ☒ The Commissioner is hereby authorized to charge payment of the following fees associated with this communication or credit any overpayment to Deposit Account No. 19-0033. A duplicate copy of this sheet is enclosed.
- ☒ Any additional filing fees required under 37 CFR §1.16.
- ☒ Any patent application processing fees under 37 CFR §1.17.

Respectfully submitted,

STEPHEN E. ACKERMAN, REG. NO. 37,761

Under the Dependence Declaration Act of 1995, no person is required to respond to a selection of information unless it displays a valid OMB control number.

**STATEMENT CLAIMING SMALL ENTITY STATUS

Title: High Performance Sub-System Design And Assembly

As a below named inventor, I hereby state that I qualify as an independent inventor as defined in 37 CFR 1.9(c) for purposes of paying reduced fees to the Patent and Trademark Office described in:

- ☒ the specification filed herewith with title as listed above.  
☐ the application identified above.  
☐ the patent identified above.

I have not assigned, granted, conveyed, or licensed, and am under no obligation under contract or law to assign, grant, convey, or license, any rights in the invention to any person who would not qualify as an independent inventor under 37 CFR 1.9(c) if that person had made the invention, or to any concern which would not qualify as a small business concern under 37 CFR 1.9(d) or a nonprofit organization under 37 CFR 1.9(e).

Each person, concern, or organization to which I have assigned, granted, conveyed, or licensed or am under an obligation under contract or law to assign, grant, convey, or license any rights in the invention is listed below:

- ☒ No such person, concern, or organization exists.  
☐ Each such person, concern, or organization is listed below.

Separate statements are required from each named person, concern, or organization having rights to the invention stating their status as small entities. (37 CFR 1.27)

I acknowledge the duty to file, in this application or patent, notification of any change in status resulting in loss of entitlement to small entity status prior to paying, or at the time of paying, the earliest of the issue fee or any maintenance fee due after the date on which status as a small entity is no longer appropriate (37 CFR 1.28(b)).

## High Performance Sub-System Design and Assembly

### Background of the Invention

#### Field of the Invention

This invention relates to structures and methods of assembly of  
5 integrated circuit chips into interconnected multiple chip circuits. More particularly, this invention relates to "chip-on-chip" structures connected physically and electrically.

#### Description of the Related Art

10 The manufacture of embedded Dynamic Random Access Memory (DRAM) requires that process parameters that enhance the performance of the logic or the DRAM, if separately formed on semiconductor chips, be compromised when DRAM is embedded into an array of logic gates on the same semiconductor chip. This compromise has limited the application of  
15 embedded DRAM. If there is no compromise in the process parameters to enhance the performance of logic or the DRAM embedded DRAM, the manufacture process becomes very complicated and costly. Moreover, because of the structure of the embedded DRAM and the logic, burn-in of the embedded DRAM is not possible and embedding of DRAM with logic  
20 is not a reliable design solution.

A "chip-on-chip" structure is a viable alternative to embedded DRAM. With multiple chips connected in intimate contact, the process parameters that maximize the performance of the DRAM chip and the logic gates can be applied during manufacture. Refer to Fig. 1 for a description of a "chip-on-chip" structure **100**. Such a "chip-on-chip" structure is described in U.S. Patent 5,534,465 (Frye et al.). A first integrated circuit chip **105** is attached physically and electrically to a second integrated circuit chip **110** by means of an area array of solder bumps **115**. The process of forming an area array of solder bumps **115** is well known in the art and is discussed in Frye et al. 465. The second chip **110** is then secured physically to a substrate **120**. Electrical connections **125** between the second integrated circuit chip **110** and external circuitry (not shown) are created as either wire bonds or tape automated bonds. The module further has a ball grid array **130** to secure the structure to a next level of packaging containing the external circuitry. Generally, an encasing material **135** is placed over the "chip-on-chip" structure **100** to provide environmental protection for the "chip-on-chip" **100**.

U.S. Patent 5,481,205 (Frye et al.) teaches a structure for making temporary connections to integrated circuit chips having "solder bumps" or connection structures such as ball grid arrays. The temporary connections allow temporary contacting of the integrated circuit chip during testing of the integrated circuit chip.

The handling of wafers from which the integrated circuit chips are formed and the handling of the integrated circuit chip themselves causes the integrated circuit chips to be subjected to electrostatic discharge (ESD) voltages. Even though connections between the first integrated circuit chip **105** and the second integrated circuit chip **110** are relatively short and under normal operation would not be subjected to ESD voltages, require ESD protection circuitry to be formed within the interchip interface circuit to provide protection or necessary driving capacity for the first integrated circuit chip **105** and the second integrated circuit chip **110** during burn-in and other manufacturing monitoring processes.

U.S. Patent 5,731,945 and U.S. Patent 5,807,791 (Bertin et al.) teach a method for fabricating programmable ESD protection circuits for multichip semiconductor structures. The interchip interface circuit on each integrated circuit chip is formed with an ESD protection circuit and a switch to selectively connect the ESD protection circuit to an input/output pad. This allows multiple identical chips to be interconnected and redundant ESD protection removed.

The circuits at the periphery of integrated circuit chips generally are specialized to meet the requirements standardized specifications. These include relatively high current and voltage drivers and receivers for

communicating on relatively long transmission line media. Alternately, as shown in U.S. Patent 5,461,333 (Condon et al.) the interface may be differential to allow lower voltages on the transmission line media. This requires two input/output pads for transfer of signals.

5

U.S. Patent 5,818,748 (Bertin et al.) illustrates a separation of chip function onto separate integrated circuits chips. This allows the optimization of the circuits. In this case, EEPROM is on one integrated circuits chip and drivers and decoders are on another. The chips are placed face to face and secured with force responsive self-interlocking micro-connectors.

10

Figs. 2a and 2b show multiple "chip-on-chip" structures **100** constructed on a wafer. Not shown is the forming of the first integrated circuit chip on a silicon wafer. The first integrated circuit chip is tested on the wafer and nonfunctioning chips are identified. The wafer is separated into the individual chips. The functioning first integrated circuit chips **105** then are "flip-chip" mounted on the second integrated circuit chip **110** on the wafer **200**. The wafer **200** is then separated into the "chip-on-chip" structures **100**. The "chip-on-chip" structures **100** are then mounted on the modules as above described.

15

20

## Summary of the Invention

An object of this invention is to provide a multiple integrated circuit chip structure where the interchip communication between integrated circuit chips of the structure have no ESD protection circuits and no input/output circuitry. The  
5 interchip communication is between internal circuits with a minimal electrical load.

Another object of this invention is to provide a circuit to selectively connect internal circuits of the integrated circuits to test interface circuits having ESD  
10 protection circuits and input/output circuitry designed to communicate with test systems during assembly and test.

To accomplish these and other objects, a multiple interconnected integrated circuit chip structure has a first integrated circuit chip mounted a  
15 second integrated circuit chip to physically and electrically connect the first integrated circuit chip to the second integrated circuit chip. The first integrated circuit chip may be mounted to the second integrated circuit chip by means of an area array of solder bumps. The first integrated circuit chip has interchip interface circuits connected to the second integrated circuit chip to communicate  
20 between internal circuits of the first and second integrated circuit chips and test circuits. The test circuits are connected to the internal circuits of the first integrated circuit chip to provide stimulus and response to the internal circuits during testing procedures.

The second integrated circuit chip has input/output interface circuitry to communicate with external circuitry connected to the second integrated circuit chip and to protect the second integrated circuit chip from electrostatic discharge voltages. Further, the second integrated circuit has interchip interface circuits connected to the first integrated circuit chip to communicate between the internal circuits of the first and second integrated circuit chips, and with test circuits. The test circuits are connected to the internal circuits of the second integrated circuit chip to provide stimulus to and response from the internal circuits during testing and burn-in procedures.

The interchip interface circuitry has an internal interface circuit for transferring electrical signals between the internal circuits of the second integrated circuit chip to the first integrated circuit chip. The interchip interface circuitry further has a mode select switch to selectively connect between the internal circuits of the first integrated circuits chip and the second integrated circuits chip or to the test interface circuits. The mode switch has three terminals and a control terminal. The first terminal is connected to an output of the internal interface circuit, a second terminal connected to the internal circuitry, and the third terminal connected to test circuits. A mode selector is connected to the control terminal. The state of the mode selector determines the connection between the first terminal and thus the output of the internal interface circuit, the second terminal and thus the internal circuitry, and the third terminal and thus the

test interface. During normal operation, the first terminal is connected to the second terminal such that the internal circuits of the first and second integrated circuits are connected through their respective internal interfaces. During test and burn-in, the internal circuits are connected to the test circuits.

5

The test circuits are formed of a test interface circuit and an ESD protection device. The test interface circuit connected to communicate test signals from external test circuitry to the first and second integrated circuit chips. The ESD protection device protects the first and second integrated circuit chips from electrostatic discharge voltages. The test interface circuit is connected to the external test circuitry through an input/output pad temporarily connected to the external test circuitry during test and burn-in.

10

15

The first integrated circuit chip could be fabricated using a first type of semiconductor process and the second integrated circuit chip would be fabricated with a second type of semiconductor process that is not compatible with the first type of semiconductor process. As an example, the first integrated circuit chip could be an array of memory cells and the second integrated circuit chip would contain electronic circuitry formed with a process not compatible with a process of the array of memory cells. Alternatively, the second integrated circuit chip is an array of memory cells and the first integrated circuit chip contains electronic circuitry formed with a process not compatible with a process of the array of memory cells. Fabricating the first integrated circuit chip using its

20

optimum semiconductor process, fabricating the second integrated circuit chip using its optimum semiconductor process, and then joining the first and second integrated circuit chips by this invention creates a multiple chip integrated circuit structure having maximum performance with minimum cost.

5

### Brief Description of the Drawings

Fig. 1 shows a cross-sectional view of a “chip-on-chip” structure of the prior art.

10

Figs. 2a and 2b are respectively top view and a cross-sectional view of a “chip-on-chip” structure formed on a semiconductor wafer of the prior art.

Fig. 3 is a cross-sectional view of a “chip-on-chip” structure, schematically the circuitry contained on each chip of the chip-on-chip structure of this invention.

15

Figs. 4 a-d are schematics of the interchip interface circuits of this invention.

Figs. 5a and 5b are schematic drawings of an embodiment of the interchip interface of this invention.

20

Figs. 6a and 6b are top surface views of the first and second integrated circuit chips of Fig. 3 showing test pads and interchip input/output pads of this invention.

5

## Detailed Description of the Invention

A "chip-on-chip" structure **300** is shown in Fig. 3. A first integrated circuit chip **305** is attached to a second integrated circuit chip **310** by means of an area array of solder bumps **315** as described above. The second integrated circuit chip **310** is secured physically to the module **320**. The electrical connections **325** are either wire bonds or TAB bonds. The module **320** has a ball grid array **330** to attach the "chip-on-chip" structure within the module to a next level of electronic package.

The first integrated circuit chip **305** has internal circuits **335**, which are the functional electronic components of the first integrated circuit chip **305**. The internal circuits **335** may be DRAM, logic, or other integrated circuits. Likewise, the second integrated circuit chip **310** has the internal circuits **365**. The internal circuits **365** are the functional electronic components of the second integrated circuit chips **310**. These internal circuits also may be DRAM, logic, or other integrated circuits. To transfer signals between the internal circuits **335** of the first integrated circuit chip **305** and the internal circuits **365** of the second chip **310** or to an external test system, the internal circuits **335** are connected to the interchip interface circuits **340**. The interchip interface circuits **340** are connected

through the input/output pads **345** to the area array of solder bumps **315** and thus to the second chip **310**. This connection is functional during normal operation, when the first integrated circuit chip **305** is mounted to the second integrated circuit chip **310**.

5

The interchip interface circuit **340** also is connected to the test interface **350**. The test interface circuit **350** is connected to the test input/output pads **355**. The test interface circuit **350** is functionally active during testing procedures, when test system probes are brought in contact with the test input/output pads **355**. The test system probes provide test stimuli and receive response from the internal circuits **335**.

10

The mode select **390** for the first integrated circuit chip **305** is accomplished by placing an appropriate logic level on the mode select input/output pads **391** and **392**. When the first integrated circuit chip **305** is in contact with a test system during wafer testing or die testing during burn-in, the mode select input/output pad **391** is brought to a first logic level (0) to cause the interchip interface circuit **340** to transfer signals between the internal circuits **335** and the test interface **350**. The test signals are then transferred between the test interface **350** and the test input/output pad **355** as described above.

15

20

When the first integrated circuit chip **305** is mounted to the second integrated circuit chip **310**, the mode select line **390** is brought to a second logic

level (1) through the mode select input/output pad **392**. The second logic level (1) is a voltage equal to the power supply voltage source  $V_{DD}$  and is achieved by connecting the mode select input output pad **392** to the mode select input/output pad **393** on the second integrated circuit chip **310** through the solder ball **394**.

- 5 The mode select input/output pad **393** is connected directly to the power supply voltage source  $V_{DD}$  to achieve the second logic level (1). When the mode select line **390** is at the second logic level (1), the interchip interface **340** transfers signals of the internal circuits **335** to the input/output pads **345** to the second integrated circuit chip **310** as described above.

10

The internal circuits **365** of the second integrated circuit chip **310** likewise are connected to the interchip interface circuits **360**. The interchip interface circuits **360** are connected to the input/output pads **370** and thus to the first integrated circuit chip **310** through the area array of solder bumps **315**. The

15 interchip interface circuits **360** are connected to the test interface circuits **375**.

15

The internal circuits **365** of the second integrated circuit chip **310** are connected to the input/output interface **385**. The input/output interface is connected to the input/output pad **395**, which is connected to the module **320**

20 through the bondwire **325**. The input/output interface provides the circuitry to transfer signals between the internal circuits **365** and the external circuits attached through the next packaging level to the ball grid array **330** and thus to the wirebond **325**.

The second integrated circuit chip **310** is tested prior to separation of a wafer containing the second integrated circuit chip **310**, by bringing test probes or needles of the test system in contact with the input/output pads **395** and the test input/output pads **377**. Subsequent to dicing of the wafer into individual second integrated circuit chips **310**, the individual second integrated circuit chips **310** are mounted in a burn-in apparatus. The burn-in apparatus again is brought in contact with the input/output pads **395** and the test input/output pads **377** to provide stressing signals to the circuits of the second integrated circuit chip **310**.

Then, when the first integrated circuit chip **305** is mounted to the second integrated circuit chip **310**, operation of the whole "chip-on-chip" assembly **300** is verified by attaching testing probes or contacts to the ball grid array **330**. Signals from the testing probes are transferred between the circuits of the whole "chip-on-chip" assembly **300** through the bond wires **325** to the input/output pads **395**.

The mode select **380** for the second integrated circuit chip **310** is accomplished by placing an appropriate logic level on the mode select input/output pads **381** and **382**. When the second integrated circuit chip **310** is in contact with a test system during wafer testing or die testing during burn-in, the mode select input/output pad **381** is brought to a first logic level (0) to cause the interchip interface circuit **360** to transfer signals between the internal circuits **365** and the test interface **375**. The test signals are then transferred between the test interface **375** and the test input/output pad **377** as described above.

When the first integrated circuit chip **305** is mounted to the second integrated circuit chip **310**, the mode select line **380** is brought to a second logic level (1) through the mode select input/output pad **382**. The second logic level (1) is achieved by connecting the mode select input output pad **382** to the mode select input/output pad **383** on the second integrated circuit chip **310** through the solder ball **384**. The mode select input/output pad **383** is connected directly to the power supply voltage source  $V_{DD}$  to achieve the second logic level (1). When the mode select line **380** is at the second logic level (1), the interchip interface **360** transfers signals of the internal circuits **365** to the input/output pads **370** to the first integrated circuit chip **305** as described above.

The input/output interface circuit **385** has an input/output buffer **389** connected to the internal circuits **365**. The input/output buffer **389** is either a driver or receiver necessary to translate the signal levels of the internal circuits **365** to the signal levels of the external circuits and the signal levels of the external circuits to the signal levels of the internal circuit **365**. The input/output buffer is connected to the input/output pad **395** and to the ESD protection circuit **387**. The ESD protection circuit **387** clamps excess ESD voltages to prevent damage to the input/output buffer **389** and the internal circuits **365** from ESD voltages brought in contact with the input/output pad **395** from the external environment.

Figs. 4a and 4d show schematically the connections of the interchip interface **340** and the test interface **350** of the first integrated circuit chip **305** of Fig. 3. Fig. 4a illustrates a path of a signal originated within the internal circuits **400** of the first integrated circuit chip and Fig. 4d illustrates a path of a signal originated externally and received by the internal circuits **462** of the first integrated circuit chip.

Referring now to Fig. 4a, the interchip interface **340** is comprised of a mode switch **402** and a mode selector **404**. The signal **400** originating from the internal circuit of the first integrated circuit chip is connected to a first terminal of the mode switch **402**. The second terminal of the mode switch **402** is connected directly to an input/output pad of the first integrated circuit chip and thus to the internal circuits of the second integrated circuit chip, as described above. The third terminal of the mode switch **402** is connected to the test interface **350**. The test interface circuit **350** is composed of the test circuit **406** connected to an input of a driver circuit **410**.

The output of the driver circuit is connected to a test input/output pad **412** and to the ESD protection circuit **414**. The ESD protection circuit **414** operates as the ESD protection circuit **387** of Fig. 3 and clamps excessive ESD voltage to protect the test interface circuit **350** from damage during handling of the wafer containing the first integrated circuit chip for manufacturing, assembly, and testing.

The control terminal of the mode switch **402** is connected to a mode selector **404** to control the function of the interchip interface **340**. When the mode selector **404** is at a first logic state, the internal circuits **400** of the first integrated circuit chip are connected to the input/output **408** and thus to the internal circuits of the second integrated circuit chip. When the mode selector **404** is at a second logic state, the internal circuits **400** of the first integrated circuit chip are connected to the test interface circuit **350**. The mode selector **404** is set to the second state during the testing procedures of the wafer containing the first integrated circuit chip. Conversely, when the mode selector **404** is set to the first logic state during the normal operation of the “chip-on-chip” structure.

Referring to Fig. 4d, the signals originating in the internal circuits of the second integrated circuit chip are transferred to the chip pad **454** of the first integrated circuit. The chip pad **454** is connected to the first terminal of the mode switch **456**. The test interface circuit **350** is connected to the second terminal of the mode switch **456**. The third terminal of the mode switch **456** is connected to the internal circuits **462** of the first integrated circuit chip. The control terminal of the mode switch **456** is connected to the mode selector **458** to control the function of the interchip interface **340**. If the control terminal of the mode switch **458** is at the first logic state, the chip pad **454** of the first integrated circuit chip and thus internal circuits of the second integrated circuit chip are connected to

the internal circuits of the first integrated circuit chip. Conversely, if the control terminal of the mode switch **458** is at the second logic state, the test interface circuit **350** is connected to the internal circuit of the first integrated circuit chip.

5           As described above, the mode selector **458** is set to the second logic state during the testing procedures of the wafer containing the first integrated circuit chip and the mode selector **458** is set to the first logic state during the normal operation of the "chip-on-chip" structure.

10           Figs. 4b and 4c show schematically the connections of the interchip interface **360** and the test interface **375** of the second integrated circuit chip **310** of Fig. 3. Fig. 4b illustrates a path of a signal originated within the internal circuits **430** of the second integrated circuit chip and Fig. 4c illustrates a path of a signal originated externally and received by the internal circuits **432** of the  
15           second integrated circuit chip.

Fig. 4b shows the instance where the signals originate on the first integrated circuit chip and are transferred through to the input/output pad **422** of the second integrated circuit chip. The input/output pad **422** is connected to the  
20           first terminal of the mode switch **424**. The test interface circuit **375** is connected to the second terminal of the mode switch **424**. The third terminal of the mode switch **424** is connected to the internal circuits **430** of the second integrated circuit chip. The control terminal of the mode switch **424** is connected to the

mode selector **426**, which operates as described above. If the mode selector **426** is at the first logic state, the signals from the internal circuit of the first integrated circuit chip are connected through the input/output pad **422** to the internal circuits **430** of the second integrated circuit chip. Alternately, if the mode selector is at the second logic state, the test signals from an external test system are transferred through the test interface **350** to the internal circuits **430** of the second integrated circuit chip. Again, as described above, the mode selector **426** is set to the first logic state during normal operation and is set to the second logic state during testing procedures.

The test interface is similar to that described in Fig. 4d. The test signals originating in an external test system are applied to a test input/output pad **416**. The test input/output pad **416** is connected to a receiver **420** an ESD protection circuit **418**. The receiver **420** translates the test signals to signal levels acceptable by the test circuit **428** and the internal circuits **430** of the second integrated circuit chip.

The ESD protection circuit **418** clamps ESD voltages applied to the test pad **416** to prevent damage to the second integrated circuit chip. The test circuits **428** format the test signals for application to the internal circuits **436** of the second integrated circuit chip.

Fig. 4c shows the instance where the signals originate in the internal circuits **432** of the second integrated circuit chip and are transferred through chip pad **438** to the first integrated circuit chip. The first terminal of the mode switch **436** receives the signals from the internal circuits **432** of the second integrated circuit chip. The second terminal of the mode switch **436** is connected to the chip pad **438**. The third terminal is connected to the test interface **375**. The control terminal is connected to the mode selector **434**.

As described above, the mode selector **434** determines the connection of the internal circuits **432** to either the chip pad **438** or the test interface circuit **375**. If the mode selector **434** is at the first logic state, the internal circuits **432** are connected through the chip pad **438** to the internal circuits of the first integrated circuit chip. Alternately, if the mode selector **434** is set to the second logic state, the internal circuits **432** are connected to the test interface circuit **375**.

The mode selector **434** is set to the first logic state during normal system operation and to the second logic state during testing procedures.

Figs. 5a and 5b illustrate the structure of an embodiment of the mode switch and the mode selector shown in Figs. 3 and 4 a-d. Fig. 5a shows the mode switch **500** and mode selector **520** for signals originated from the internal circuits **508** from the first or second integrated circuit chips. Alternately, Fig. 5b shows the mode switch **500** and mode selector **520** for signals originated

externally and transferred to the internal circuits **508** of the first or second integrated circuit chips.

Referring now to Fig. 5a, the first terminal of the mode switch **500** is  
5 connected to the internal circuits **508**, the second terminal of the mode switch **500** is connected to the test interface circuit **510** and the third terminal of the mode switch **500** is connected to the interchip input/output pad **530**.

The mode switch is comprised of the pass switches **502** and **504** and  
10 inverter **506**. The pass switch **502** is the parallel combination of the n-channel metal oxide semiconductor (NMOS) transistor **502a** and p-channel metal oxide semiconductor (PMOS) transistor **502b**. Likewise, the pass switch **504** is the parallel combination of the NMOS transistor **504a** and the PMOS transistor **504b**.  
The first terminal of the mode switch **500** and thus the internal circuits **508** are  
15 connected to the drains of the pass switches **502** and **504**. The sources of the pass switch **502** are connected to the third terminal of the mode switch **500** and thus to the interchip input/output pad **530**. The sources of the pass switch **504** are connected to the second terminal of the mode switch **500** and thus to the test interface circuit **510**. The gates of the NMOS transistor **504a** and the PMOS transistor **502b** are connected to the output of the inverter **506**. The gates of the  
20 NMOS transistor **502a**, PMOS transistor **504b**, and the input of the inverter **506** are connected to the control terminal of the mode switch **500** and thus to the mode selector **520**.

When the control terminal of the mode switch **500** is at the first logic state, in this case a voltage level approaching that of the power supply voltage source  $V_{DD}$ , the pass switch **502** is turned on and the pass switch **504** is turned off. This effectively connects the internal circuits **508** to the interchip input/output pad **530**.  
 In this logic state, the extra electrical load is from the drain of the pass switch **502** and the pass switch **504**. This electrical load is very small and thus highly improved performance can be expected over the prior art. Conversely, when the control terminal of the mode switch **500** is at the second logic state, in this case a voltage level approaching that of the substrate biasing voltage source  $V_{ss}$ , the pass switch **504** is turned on and the pass switch **502** is turned off. The internal circuits are now effectively connected to the test interface circuit **510**.

The test interface circuit **510** is comprised of the test circuit **512**, the driver circuit **514**, and the ESD protection circuit **516**. The test interface circuit functions as described in Figs. 4a and 4c.

The mode select circuit is the interchip input/output pad **522** and the test input/output pad **524** connected together and to the control terminal of the mode switch **500**. The interchip input/output pad **522** is connected as described in Fig. 3 to a mating interchip input/output pad **562** that are joined by a solder bump or ball. The mating interchip input/output pad **562** is on the mating chip **560** and is connected to the power supply voltage source  $V_{DD}$  to provide the first logic state

to the control terminal of the mode switch **500** during normal operation. The test input/output pad is connected to the test system **550** during the testing procedures. During the test procedures, a test probe or needle **552** is brought in contact with the test input/output pad. The test probe or needle **552** is connected  
5 on a probe card **554** within the test system **550** to the substrate biasing voltage source  $V_{ss}$  to provide the second logic state to the control terminal of the mode switch **500**.

The fundamental connections shown in Fig. 5b are as described in Fig. 5a  
10 except the test signal originates from the test system attached to the input/output pad **540**. The test interface circuit **510** in this case is comprised of the test circuits **512**, the receiver **518**, and the ESD protection circuit and functions as described in Figs. 4b and 4d.

15 Signals originating from the external circuits are applied to the interchip input/output pad **530** and transferred through the pass switch **502** to the internal circuits **508** during normal operation. Likewise, the test signals are transferred from the test interface **510** through the pass switch **504** to the internal circuits **508** during the test procedures.

20

Fig. 6a shows a top surface view of the first integrated circuit chip **600** illustrating the placement of the test input/output pads **605** and the interchip input/output pads **610**. The interchip input/output pads **610** form an area array of

solder balls or bumps **315** of Fig. 3. The test input/output pads **605** are peripherally arranged so that the test probes or needles of the test system can conveniently make contact with the test input/output pads **605**.

Fig. 6b shows the top surface view of the second integrated circuit chip **615** illustrating the placement of the interchip input/output pads **625** and the external input/output pads **620**. The interchip input/output pads **625** form the area array to mate with the interchip input/output pads **610** of Fig. 5a. The first integrated circuit chip **600** is mounted "face-to face" to the second integrated circuit chip **615**. The test input/output pads **605** must have nothing on the surface of the second integrated circuit chip **625** in their "shadow."

The test input/output pads **630** and the external input/output pads **620** are formed in the periphery of the second integrated circuit chip **615**. The external input/output pads **620** must be placed outside the shadow of the first integrated circuit chip **600**. The test input/output pads **630** are placed conveniently so that test probes or needles of a test system can contact the test input/output pads **630**. The test input/output pads **605** and **630** are connected as shown in Figs. 5a and 5b to the test interface **510**. The test input/output pads **605** and **630** transfer stimulus and response signals between the test system **550** and either the first integrated circuit chip **600** or second integrated circuit chip **615**.

While this invention has been particularly shown and described with reference to the preferred embodiments thereof, it will be understood by those skilled in the art that various changes in form and details may be made without departing from the spirit and scope of the invention.

5

The invention claimed is:

1. A multiple interconnected integrated circuit chip structure comprising a first integrated circuit chip and a second integrated circuit chip comprising:

whereby the first integrated circuit chip is mounted to the second chip to physically and electrically connect the first integrated circuit chip to the second integrated circuit chip;

whereby the first integrated circuit chip has interchip interface circuits connected to the second integrated circuit chip to selectively communicate between internal circuits of the first and second integrated circuit chips and test circuits connected to internal circuits of the first integrated circuit chip to provide stimulus and response to said internal circuits;

whereby the second integrated circuit chip has input/output interface circuitry to communicate with external circuitry connected to said second integrated circuit chip and to protect said second integrated circuit chip from electrostatic discharge voltages;

whereby the interchip interface circuitry comprises:

an internal interface circuit for transferring electrical signals between the second integrated circuit chip and the first integrated circuit chip;

a mode select switch having a first terminal connected to an input/output pad, a second terminal connected to the

internal circuitry of the integrated circuit chip, a third terminal connected to test circuits, and a mode selector to selectively connect the output of the internal interface circuit to the internal circuitry of the first integrated circuit chip during normal operation and the output of the internal interface circuit to the test circuitry during test and burn-in.

2. The chip structure of claim 1 wherein the second integrated circuit chip further has interchip interface circuits connected to the first integrated circuit chip to selectively communicate between internal circuits of the first and second integrated circuit chips and test circuits connected to internal circuits of the second integrated circuit chip to provide stimulus and response to said internal circuits.
3. The chip structure of claim 1 wherein the first chip is mounted to the second chip by means of an area array of solder bumps.
4. The chip structure of claim 1 wherein the test circuits comprise:
  - test interface circuits connected to external test circuitry to communicate with said external test circuitry and
  - ESD protection circuits to protect said first and second integrated circuit chips from electrostatic discharge voltages.

5. The chip structure of claim 1 wherein the first integrated circuit chip is fabricated using a first type of semiconductor process and the second integrated circuit chip is fabricated with a second type of semiconductor process that is not compatible with the first type of semiconductor process.  
5
6. The chip structure of claim 1 wherein the first integrated circuit chip is an array of memory cells and the second integrated circuit chip contains electronic circuitry formed with a process not compatible with a process of the array of memory cells.  
10
7. The chip structure of claim 1 wherein the second integrated circuit chip is an array of memory cells and the first integrated circuit chip contains electronic circuitry formed with a process not compatible with a process of the array of memory cells.  
15
8. The chip structure of claim 4 wherein the test interface circuit is connected to the external test circuitry through an input/output pad temporarily connected to said external test circuitry during test and burn-in.  
20
9. The chip structure of claim 1 wherein the interchip interface circuit has no electrostatic discharge protection circuit.

10. The chip structure of claim 1 wherein the internal interface circuit is not capable of communication with the external circuitry.

11. The chip structure of claim 1 wherein the mode switch comprises:

5 a first pass switch having a drain terminal connected to the internal circuits, a source terminal connected to an input/output pad connected to an attached integrated circuit chip, a first gate terminal connected to the mode selector, and a second gate terminal;

10 a second pass switch having a drain terminal connected to the internal circuits, a source terminal connected to the input/output pad connected to the attached integrated circuit chip, a first gate terminal, and a second gate terminal connected to the mode selector;

15 an inverter circuit having an input terminal connected to the mode selector and an output terminal connected to the second gate terminal of the first pass switch and the first gate of the second pass switch.

20 12. The chip structure of claim 10 wherein the first and second pass switches are comprised of an NMOS transistor and PMOS transistor connected in parallel with a gate of the NMOS transistor being the first gate terminal of

the first and second pass switches and a gate of the PMOS transistor being the second gate terminal of the first and second pass switches.

13. The chip structure of claim 1 wherein in the mode switch comprises:

- 5           an interchip input/output pad connected to a first logic state generator during normal operation;
- a test input/output pad connected to a second logic state generator during testing procedures.

10   14. An interchip interface circuit formed in multiples upon a first and second integrated circuit chip for communication between internal circuits of the first and second integrated circuit chip;

          whereby said first integrated circuit chip is attached physically and electrically to said second integrated circuit chip; and

15           whereby said interchip interface circuit comprises:

          an internal interface circuit for transferring electrical signals between the second integrated circuit chip to the first integrated circuit chip;

          a mode select switch having a first terminal connected to an output of the internal interface circuit, a second terminal connected to the internal circuitry of one of the integrated circuit chip, a third terminal connected to test circuits, and a control terminal; and

20

a mode selector connected to the control terminal to  
selectively connect the output of the internal interface  
circuit to the internal circuitry of the integrated circuit chips  
during normal operation and the output of the internal  
5 interface circuit to the test circuitry during testing  
procedures.

15. The interface circuit of claim 14 wherein the first chip is attached to the  
second chip by means of an area array of solder bumps.
- 10 16. The interface circuit of claim 14 wherein the test circuits comprise:  
test interface circuits connected to external test circuitry to  
communicate with said external test circuitry; and  
an ESD protection circuit to protect said first and second integrated  
15 circuit chips from electrostatic discharge voltages.
17. The interface circuit of claim 14 wherein the first integrated circuit chip is  
fabricated using a first type of semiconductor process and the second  
integrated circuit chip is fabricated with a second type of semiconductor  
20 process that is not compatible with the first type of semiconductor process.
18. The interface circuit of claim 14 wherein the first integrated circuit chip is  
an array of memory cells and the second integrated circuit chip contains

electronic circuitry formed with a process not compatible with a process of the array of memory cells.

19. The interface circuit of claim 14 wherein the second integrated circuit chip  
5 is an array of memory cells and the first integrated circuit chip contains electronic circuitry formed with a process not compatible with a process of the array of memory cells.

20. The interface circuit of claim 16 wherein the test interface circuit is  
10 connected to the external test circuitry through an input/output pad temporarily connected to said external test circuitry during test and burn-in.

21. The interface circuit of claim 14 wherein the interchip interface circuit has  
15 no electrostatic discharge protection circuit.

22. The interface circuit of claim 14 wherein the internal interface circuit is not capable of communication with the external circuitry.

20 23. The interface circuit of claim 14 wherein the mode switch comprises:  
a first pass switch having a drain terminal connected to the internal  
circuits, a source terminal connected to an input/output pad  
connected to an attached integrated circuit chip, a first gate

terminal connected to the mode selector, and a second gate terminal;

a second pass switch having a drain terminal connected to the internal circuits, a source terminal connected to the input/output pad connected to the attached integrated circuit chip, a first gate terminal, and a second gate terminal connected to the mode selector;

an inverter circuit having an input terminal connected to the mode selector and an output terminal connected to the second gate terminal of the first pass switch and the first gate of the second pass switch.

24. The interface circuit of claim 23 wherein the first and second pass switches are comprised of an NMOS transistor and PMOS transistor connected in parallel with a gate of the NMOS transistor being the first gate terminal of the first and second pass switches and a gate of the PMOS transistor being the second gate terminal of the first and second pass switches.

25. The interface circuit of claim 23 wherein in the mode switch comprises:  
an interchip input/output pad connected to a first logic state generator during normal operation;

a test input/output pad connected to a second logic state generator during testing procedures.

26. A method of forming a multiple integrated circuit chip structure comprising the steps of:

simultaneously but separately forming internal circuits on a first semiconductor wafer containing a plural first integrated circuit chip and a second semiconductor wafer containing a plural second integrated circuit chip;

simultaneously forming test circuits on the first wafer and the second wafer;

simultaneously forming interchip interface circuits on the first wafer and the second wafer, whereby forming said interchip interface circuit comprises the steps of:

forming an internal interface circuit for transferring electrical signals between the second integrated circuit chip to the first integrated circuit chip;

forming a mode select switch having a first terminal connected to an output of the internal interface circuit, a second terminal connected to the internal circuitry of the first integrated circuit chip;

forming a mode selector to selectively connect the output of the internal interface circuit to the internal circuitry of the

first integrated circuit chip during normal operation and the output of the internal interface circuit to the test circuitry during test and burn-in;

forming input/output interface circuits on said second wafer;

5 contacting, stimulating, and examining a response of the test circuits on the first wafer and the test circuits and input/output interface circuits on the second wafer;

separating the first wafer into a plurality of separated first integrated circuit chips;

10 contacting with sockets, stimulating and burning-in the plurality of separated first integrated circuit chips for an extended period of time;

contacting, stimulating, and examining the plurality of separated first integrated circuit chips;

15 discarding defective first integrated circuit chips;

attaching each functioning chip of the first integrated circuit chips to one of one functioning second integrated circuit chip on the second wafer

separating the second wafer into the plurality of second integrated circuit chips; and

20

contacting the input/output interface circuits, stimulating, and examining the response of the formed multiple integrated circuit chip structure.

27. The method of claim 26 wherein the attaching of each of the first integrated circuit chips to the second integrated circuit chips is accomplished by forming a area array of solder bumps between each of the first integrated circuit chips and the second integrated circuit chips.
28. The method of claim 26 wherein forming the test circuits comprises the steps of:
- forming test interface circuits connected to external test circuitry to communicate with said external test circuitry and
  - forming ESD protection circuitry to protect said first and second integrated circuit chips from electrostatic discharge voltages.
29. The method of claim 26 wherein the first integrated circuit chip is fabricated using a first type of semiconductor process and the second integrated circuit chip is fabricated with a second type of semiconductor process that is not compatible with the first type of semiconductor process.
30. The method of claim 26 wherein the first integrated circuit chip is an array of memory cells and the second integrated circuit chip contains electronic circuitry formed with a process not compatible with a process of the array of memory cells.

31. The method of claim 26 wherein the second integrated circuit chip is an array of memory cells and the first integrated circuit chip contains electronic circuitry formed with a process not compatible with a process of the array of memory cells.

5

32. The method of claim 26 wherein contacting the test interface circuit comprises the step of temporarily connecting external test circuitry through an input/output pad to said test interface circuit.

10 33. The method of claim 26 wherein the interchip interface circuit is formed with no electrostatic discharge protection circuit.

34. The method of claim 26 wherein the internal interface circuit is formed with no ability to communicate with the external circuitry.

15

35. The method of claim 26 wherein the mode switch comprises:

a first pass switch having a drain terminal connected to the internal circuits, a source terminal connected to an input/output pad connected to an attached integrated circuit chip, a first gate terminal connected to the mode selector, and a second gate terminal;

20

a second pass switch having a drain terminal connected to the internal circuits, a source terminal connected to the input/output

pad connected to the attached integrated circuit chip, a first gate terminal, and a second gate terminal connected to the mode selector;

an inverter circuit having an input terminal connected to the mode selector and an output terminal connected to the second gate terminal of the first pass switch and the first gate of the second pass switch.

36. The method of claim 32 wherein the first and second pass switches are comprised of an NMOS transistor and PMOS transistor connected in parallel with a gate of the NMOS transistor being the first gate terminal of the first and second pass switches and a gate of the PMOS transistor being the second gate terminal of the first and second pass switches.

37. The method of claim 24 wherein in the mode switch comprises:  
 an interchip input/output pad connected to a first logic state generator during normal operation;  
 a test input/output pad connected to a second logic state generator during testing procedures.

## Abstract

A multiple integrated circuit chip structure provides interchip communication between integrated circuit chips of the structure with no ESD protection circuits and no input/output circuitry. The interchip communication is between internal circuits of the integrated circuit chips. The multiple integrated circuit chip structure has an interchip interface circuit to selectively connect internal circuits of the integrated circuits to test interface circuits having ESD protection circuits and input/output circuitry designed to communicate with external test systems during test and burn-in procedures. The multiple interconnected integrated circuit chip structure has a first integrated circuit chip mounted a second integrated circuit chip to physically and electrically connect the first integrated circuit chip to the second integrated circuit chip. The first integrated circuit chip has interchip interface circuits connected to the second integrated circuit chip to selectively communicate between internal circuits of the first and second integrated circuit chips or test interface circuits connected to the internal circuits of the first integrated circuit chip to provide stimulus and response to said internal circuits during testing procedures. The second integrated circuit chip has input/output interface circuitry to communicate with external circuitry connected to the second integrated circuit chip and to protect said second integrated circuit chip from electrostatic discharge voltages. Further, the second integrated circuit has interchip interface circuits connected to the first integrated circuit chip to communicate between the internal circuits of the first and second integrated circuit chips.

## DECLARATION AND POWER OF ATTORNEY FOR PATENT APPLICATION

DOCKET NO. MSLIN98-00A

As a below named Inventor, I hereby declare that:

My residence, post office address and citizenship are as stated below next to my name,

I believe I am the original, first and sole inventor (if only one name is listed below) or an original, first and joint inventor (if plural names are listed below) of the subject matter which is claimed and for which a patent is sought on the invention entitled

High Performance Sub-System Design And Assembly

the specification of which (check one)

X is attached hereto

was filed on \_\_\_\_\_

Application Serial No \_\_\_\_\_

and was amended on \_\_\_\_\_

(if applicable)

I hereby state that I have reviewed and understand the contents of the above Identified specification including the claims, as amended by any amendment referred to above.

I acknowledge the duty to disclose information which is material to the examination of this application in accordance with Title 37, Code of Federal Regulations, §1.56(a).

I hereby claim foreign priority benefits under Title 35, United States Code §119 of any foreign application(s) for patent or inventor's certificate listed below and have also identified below any foreign application for patent or inventor's certificate having a filing date before that of the application on which priority is claimed.

Prior Foreign Application(s)
